W2: Building blocks / memory stores

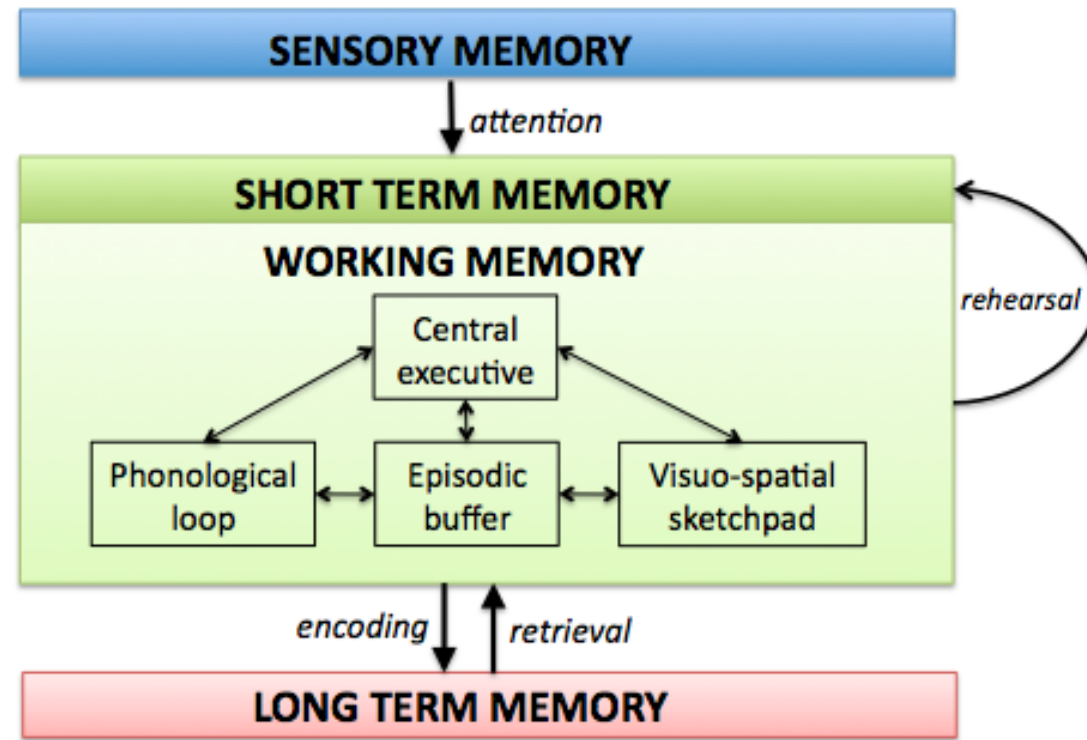

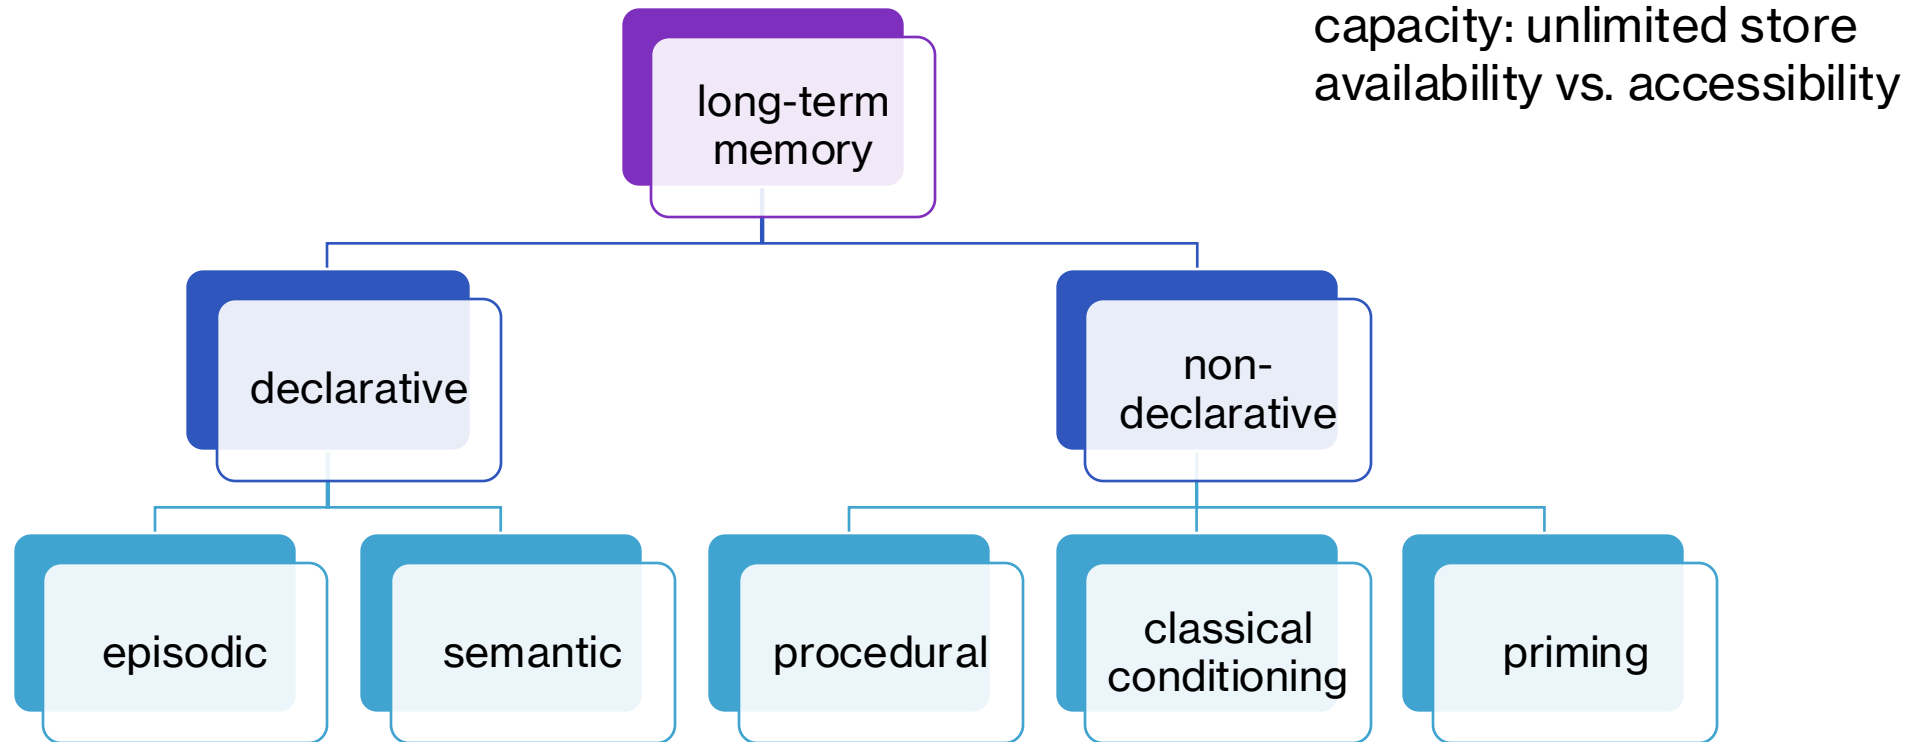

# logistics

- my office hours are from 11.45 – 2 pm this Friday

# how do we process information?

# today's agenda: long term memory

# episodic vs. semantic memory

## episodic

- memory for specific events
- situated in a time and place
- “I remember this”

## semantic

- general knowledge about the world and its entities
- decontextualized
- “I know this”

# two separate systems or one?

- evidence for **separate** systems
  - amnesic patients (e.g., KC)
  - neurodegenerative diseases (Alzheimer vs. semantic dementia)
- evidence for **single system**
  - memory tests are not “process pure”
  - meaning can be “context-dependent”
  - shared neural substrates
  - computational models

## Instance theory as a domain-general framework for cognitive psychology

Randall K. Jamieson , Brendan T. Johns, John R. Vokey and Michael N. Jones

Abstract | The dominant view in cognitive psychology is that memory includes several distinct and separate systems including episodic memory, semantic memory and associative learning, each with a different set of representations, explanatory principles and mechanisms. In opposition to that trend, there is a renewed effort to reconcile those distinctions in favour of a cohesive and integrative account of memory. According to instance theory, humans store individual experiences in episodic memory and general-level and semantic knowledge such as categories, word meanings and associations emerge during retrieval. In this Perspective, we review applications of instance theory from the domains of remembering, language and associative learning. We conclude that instance theory is a productive candidate for a general theory of cognition and we propose avenues for future work that extends instance theory into the domain of cognitive computing, builds hybrid instance models and builds bridges to cognitive neuroscience.

total correct?

# recognition task: hits and false alarms

- observing **only the correct responses** could be **misleading** if the person simply answers “old” for all items
- **hits and false alarms together** provide a **clearer picture**

	item	
response	OLD ( <b>WOMAN</b> )	NEW ( <b>QUEEN</b> )
OLD	hit	false alarm
NEW	miss	correct rejection

# understanding signal vs. noise

- this framing comes from [signal detection theory](#), that has wide applications in decision-making and statistics

	world truth	
your decision	signal	noise
signal	hit	false alarm
noise	miss	correct rejection

# activity: understanding signal vs. noise

- a researcher hypothesizes that freshman and seniors have different enrolment rates for 8AM classes. apply the signal detection idea and discuss what a hit / false alarm / miss / correct rejection would mean here

	world truth	
your experiment	effect exists	effect doesn't exist
effect found	hit	false alarm
effect not found	miss	correct rejection

# the forgetting function

- Ebbinghaus (1885) tested the **early claims of association** via experimental manipulations within the context of learning and forgetting
  - phase one: learn nonsense syllables and recite to criterion
  - phase two: lists relearned after a delay period
- Murre & Dros (2015) replicated this work
- key idea: **forgetting decreases over time**, i.e., you forget a lot initially and less and less over time

	1	2	3	4	5	6	7	8	9	10	11	12	13

# Bartlett's re-remembering metaphor

- Bartlett proposed a **reconstructive** view of memory
- two tasks, **serial reproduction**
  - **War of Ghosts**: participants wrote down a story about indigenous Americans from memory; produced predictable schemas as more time went on
    - Bergman & Roediger (1999) replicated the broad pattern
  - **L'Portraite D'homme**: participants reproduced a mask drawing from memory; their drawings became more face-like over time
    - Carbon & Albrecht (2012) were unable to replicate this pattern...why?

# today's agenda: long term memory

# how is semantic memory organized?

- account #1: **hierarchical network**
- Collins and Quillian (1969)
- principle of cognitive economy: not storing redundant information but organizing **taxonomically**
- navigating levels in the network takes time

Figure 7.12 A hierarchical network representation of concepts.

SOURCE: From Collins, A. M., & Quillian, M. R., Retrieval time from semantic memory. *Journal of Verbal Learning and Verbal Behavior*, 8, 240-247, copyright © 1969. Reprinted with permission.

# account #1: hierarchical network

- testing the model: sentence verification task (yes / no)
- is a canary a bird?
- does a canary sing?
- navigating levels in the network takes time

Figure 7.12 A hierarchical network representation of concepts.

SOURCE: From Collins, A. M., & Quillian, M. R., Retrieval time from semantic memory. *Journal of Verbal Learning and Verbal Behavior*, 8, 240-247, copyright © 1969. Reprinted with permission.

# account #1: hierarchical network

- response times increased linearly as a function of how many “levels” had to be traveled to retrieve that information

FIG. 2. Average reaction times for different types of sentences in three experiments.

# account #1: hierarchical network

- problems:
- **typicality effects**: people responded faster to “robin is a bird” than “vulture is a bird” when the model predicts no difference in response times
- **“no”/false response times** were different depending on the items  
“butterfly is a bird” was slower than “monkey is a bird”

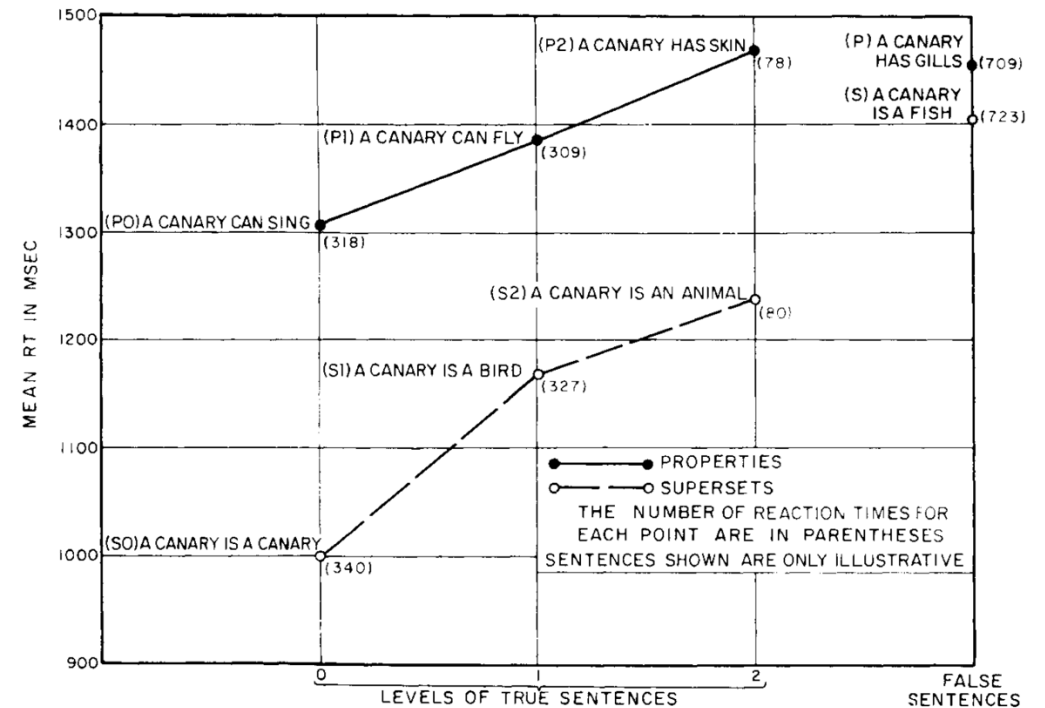

FIG. 2. Average reaction times for different types of sentences in three experiments.

# account #2: feature comparison model

- account #2: feature comparison model
- Smith, Shoben, & Rips (1973)
- **distributed representation** of each concept along a set of features/dimensions
  - defining features: all birds have wings
  - characteristic features: only some birds fly
- **overlap between features** determined response times
- was able to explain typicality effects, false RTs, etc.

# account #2: feature comparison model

- **positives:**
  - changed how concepts could be represented, i.e., a distributed representation
  - the beginning of mathematical modeling of words, language, neural networks!
- **problems:**
  - what are the features?!
  - how are they learned?!

	Robin	Eagle	Bird
Defining	$F_{i,R}$	$F_{i,E}$	$F_{i,B}$
	-	-	-
	-	-	$F_{k,B}$
	$F_{i,R}$	$F_{j,E}$

# account #3: non-hierarchical network

- account #3: non-hierarchical network
- Collins and Loftus (1975)
- concepts are organized in a semantic network, with connections being weighted by semantic similarity
- less constrained account, but how do we learn these similarities and connections?!

# testing semantic knowledge

- the closer two concepts are in semantic memory, the more likely they are to activate one another
- general paradigm: **priming** = prior processing can influence how information is accessed or retrieved
- **semantic priming**: when priming tasks are used to test semantic memory

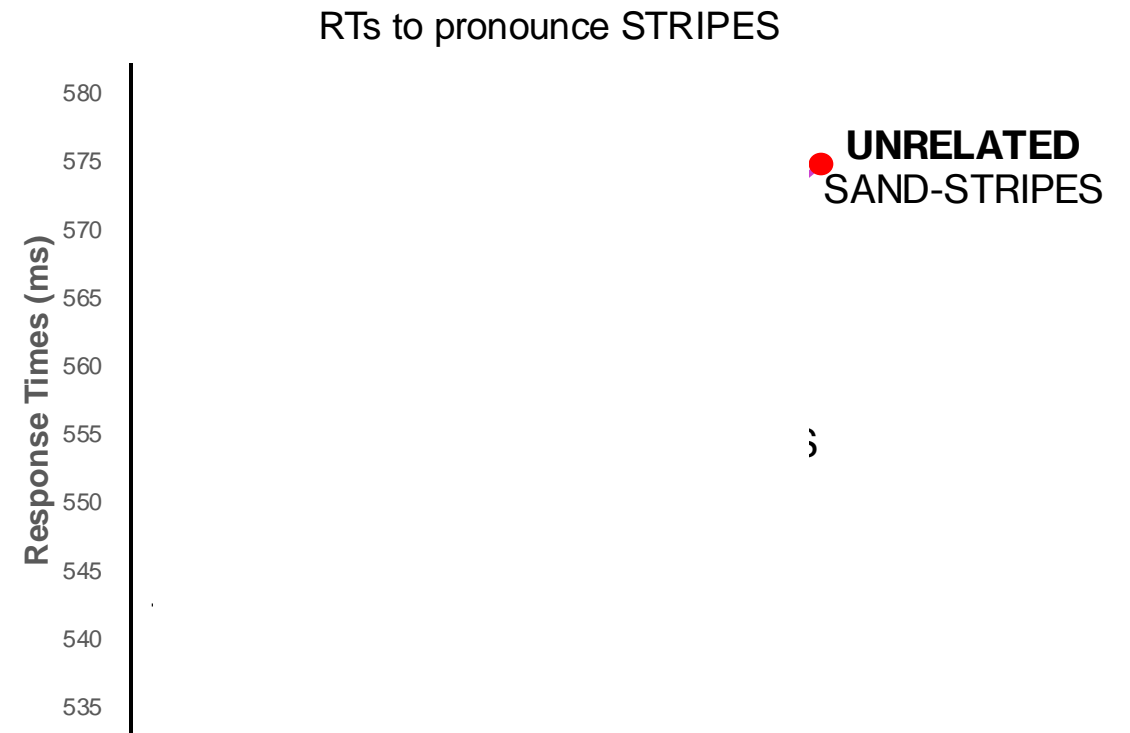

# semantic priming

- semantic priming tasks involve presenting a **prime** that may be related / unrelated to the upcoming **target** word
  - lexical decision task: deciding whether a target word is a word/non-word
  - relatedness judgment task: deciding whether two words are related or unrelated
- processing a related word speeds up or facilitates processing of the target word

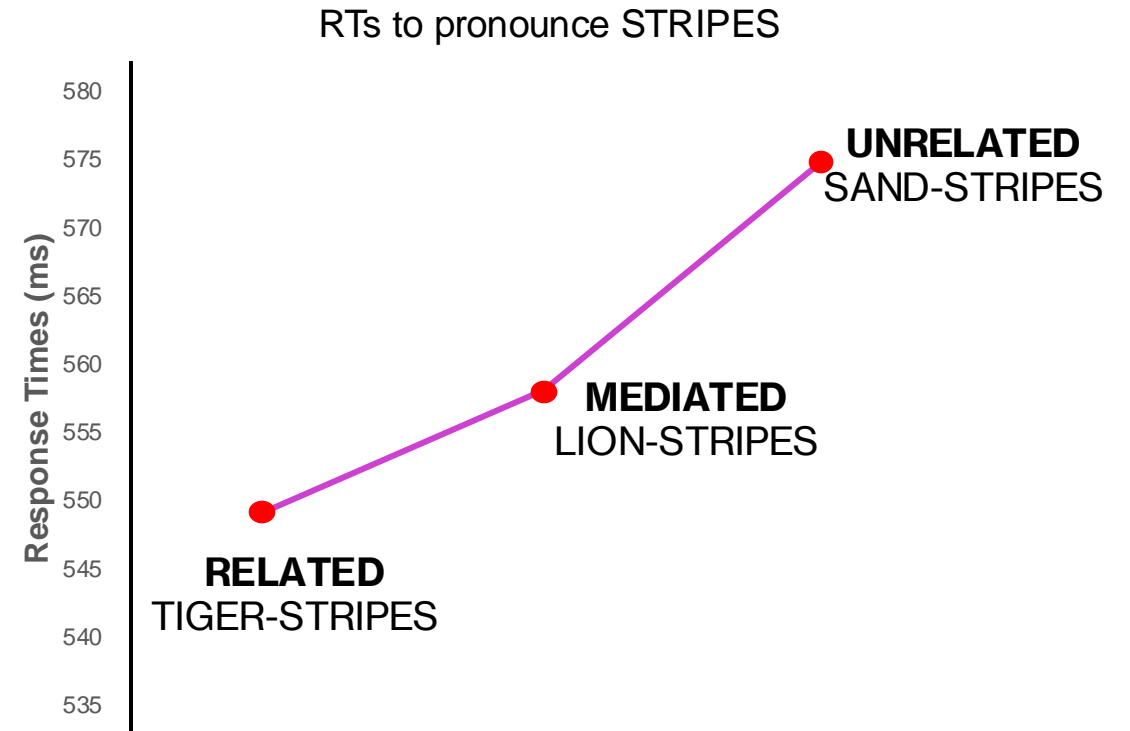

# how far does activation spread?

- **mediated priming** has been shown for items that do not seem to share a direct relationship, e.g., **lion-stripes** in pronunciation (Balota & Lorch, 1986) and lexical decision tasks (McNamara & Altarriba, 1988)

# how far does activation spread?

- potential limitations/issues:
- how do we know how close or far concepts are from one another?

# distant semantic priming

- using computational models of semantic memory to estimate “path lengths” between words

# Hybrid Correlation Network

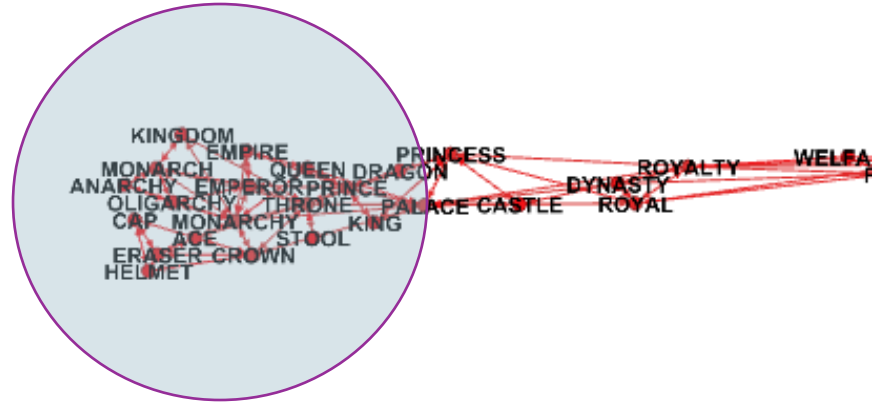

# Hybrid Correlation Network
