DATA ANALYSIS

Week 11: F-tests/ANOVAs for nominal data

lunch with Psychology faculty!

Lunch with Psychology Faculty

The Psychology Department is hosting lunches with faculty and students this semester.

All lunches will be in **Thorne Dining**! Please meet us at the check-in station at the times mentioned for the specific dates.

The lunches are on the following dates/times:

- Wednesday, February 21 2024 (**12 pm**): Prof. Erika Nyhus and Prof. Hannah Reese
- Tuesday, March 5 2024 (**12 pm**): Prof. Kacie Armstrong, Prof. Suzanne Lovett, and Prof. Thomas Small
- Friday, April 12 2024 (**1.10 pm**): Prof. Abhilasha Kumar and Prof. Samuel Putnam
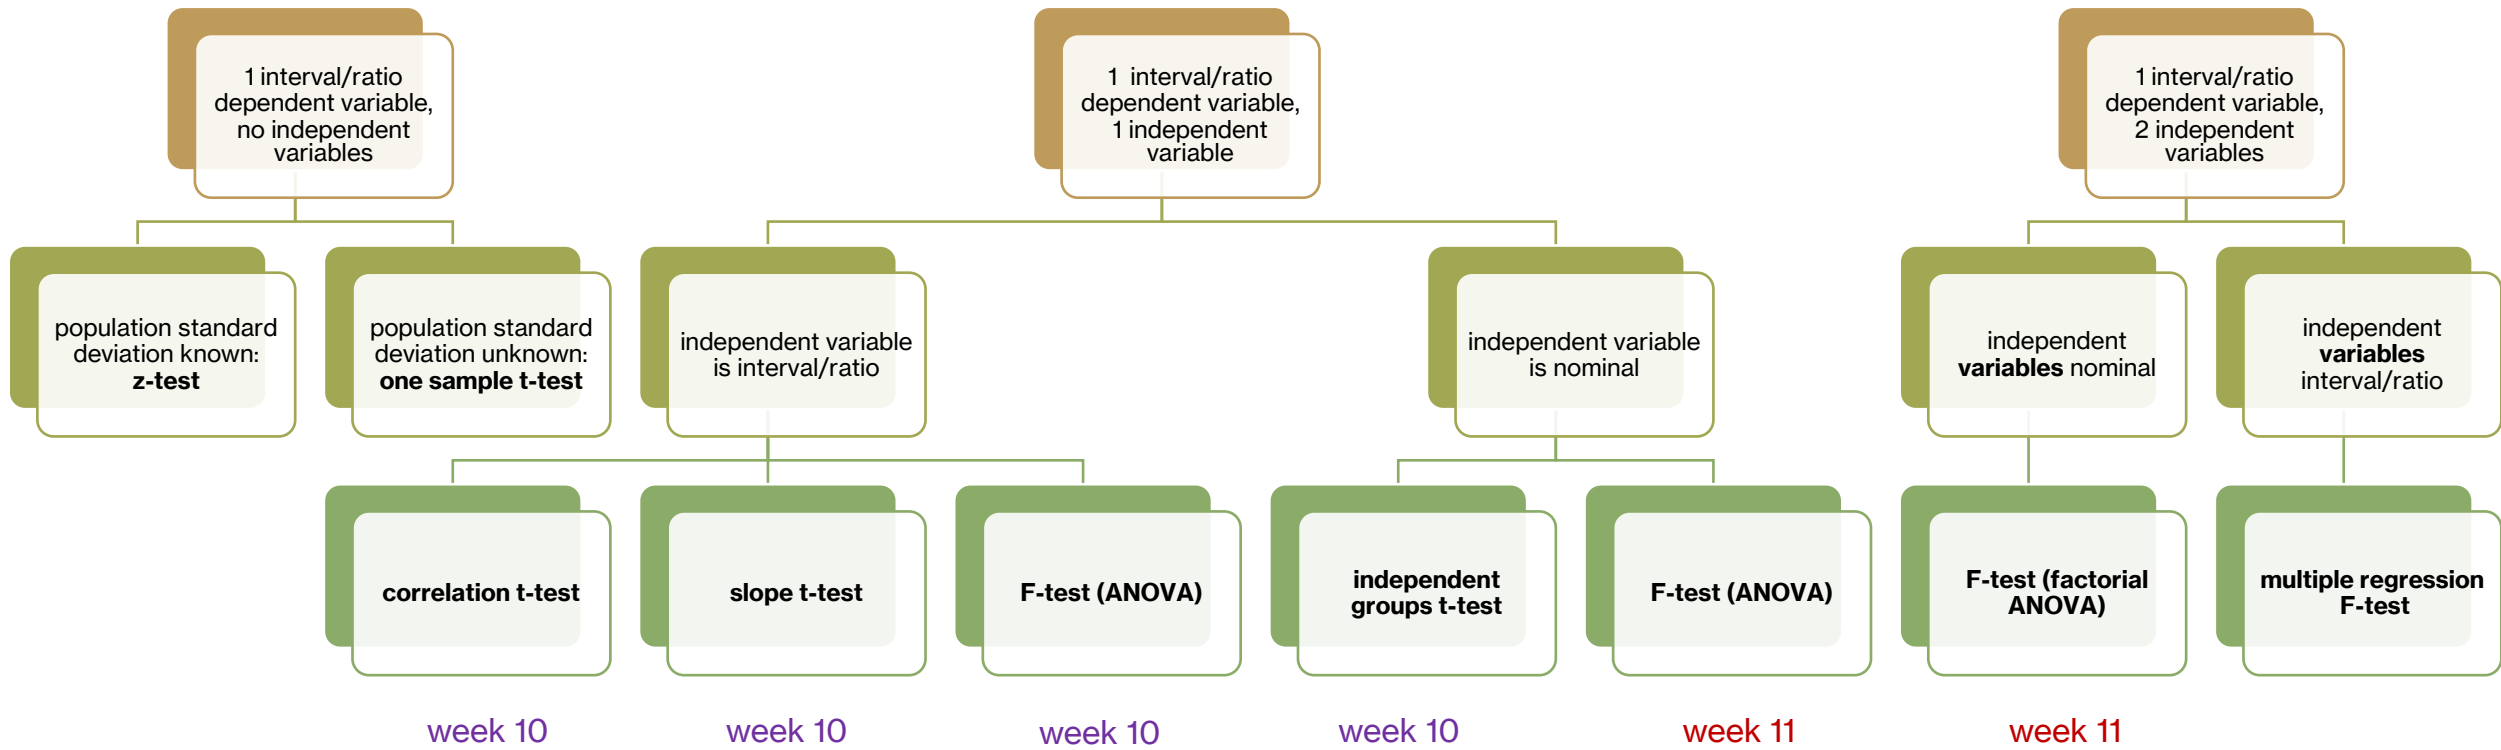

We look forward to seeing you!
logistics

- no week 11 or week 12 quiz!

- office hours only 2-4 today

- problem set #4 second attempt due tonight

- problem set #6 (due Apr 9)

- class survey (due Apr 9, Canvas)

- midterm 2 review materials (on Canvas by Friday):

  - midterm 2 practice quiz

  - midterm 2 computational questions

- Apr 10 is a review class for midterm 2

the chart of doom (so far)

week 7

| 1 interval/ratio dependent variable, no independent variables | 1 interval/ratio dependent variable, 1 independent variable | 1 interval/ratio dependent variable, 2 independent variables |

population standard deviation known: **z-test**

population standard deviation unknown: **one sample t-test**

independent variable is interval/ratio

independent variable is nominal

independent **variables** nominal

independent **variables** interval/ratio

correlation t-test

slope t-test

F-test (ANOVA)

independent groups t-test

F-test (ANOVA)

F-test (factorial ANOVA)

**multiple regression F-test**

week 10

week 10

week 10

week 10

week 11

week 11

only for two groups!

review: iris dataset

- our goal is to build the best model for petal lengths

- petal length (Y) = a + b (species:X)

- we conducted an independent groups t-test to evaluate the significance of adding a "species" mean to our model over and above the grand mean

- t-test compared the $M_{setosa} \; to \; M_{virginica}$
Iris setosa   *Iris versicolor*   *Iris virginica*

review: independent groups t-test

step 1: state the hypotheses	step 2: set criteria for decision	step 3: collect data	step 4: make a decision!

$H_0: \beta = 0$ or $\mu_2 - \mu_1 = 0$

$H_1: \beta \neq 0$ or $\mu_2 - \mu_1 \neq 0$

$\alpha = .05$
find $t_{critical}$ based on one vs. two tailed test and degrees of freedom
$df = n_1 + n_2 - 2$

(1) compute $s_{M2-M1} = \sqrt{\frac{s_p^2}{n_1} + \frac{s_p^2}{n_2}}$
and $b = M_2 - M_1$

(2) compute $t_{observed} = \frac{b - \beta}{s_{M2-M1}}$

(3) find p-value for t-score

check whether $t_{observed}$ is beyond $t_{critical}$ and p-value $< .05$. if so, reject null hypothesis!

review: independent groups t-test

- **step 1: state the hypotheses**
  - H_0: $\mu_{virginica} - \mu_{setosa} = 0$: mean petal lengths for both species are equal, i.e.,
  - H_1: $\mu_{virginica} - \mu_{setosa} \neq 0$: mean petal lengths for both species are not equal, i.e.,

- **step 2: set criteria for decision**

$$df = n_1 + n_2 - 2 = 10 + 10 - 2 = 18$$

$$t_{18} = t_{critical} = 2.1009$$

- **step 3: collect data**

$$s_p^2 = \frac{SS_1 + SS_2}{df_1 + df_2} = .0525$$

$$s_{M2-M1} = \sqrt{\frac{s_p^2}{n_1} + \frac{s_p^2}{n_2}} = .1025$$

$$b = M_2 - M_1 = 3.88$$

$$t_{observed} = \frac{b - 0}{s_{M2-M1}} = \frac{(3.88) - 0}{.1025} = 37.844 \text{ and p-value} < .0001$$

- **step 4: make a decision!**

assumptions: t-test

$$s_p{}^2 = \frac{SS_1 + SS_2}{df_1 + df_2}$$

$$s_{M2-M1} = \sqrt{\frac{s_p{}^2}{n_1} + \frac{s_p{}^2}{n_2}}$$

- interval/ratio dependent variable

- independent observations (between-subjects design)

- normality

  - when data are not normal, the t-test is not appropriate

  - BUT: t-tests are fairly robust to minor violations for large n

- homogeneity of variances

  - we assume that the populations from which samples are drawn have equal variances to compute a "pooled" estimate of variance for the independent groups t-test

  - Welch's test is done for unequal variances

questions?
F-test for two groups

- just as we did an "overall" test for linear regression, we can do the same here for the iris dataset, where we compare the grand mean model with the species mean model

- recall that $F = \dfrac{MS_{model}}{MS_{error}} = \dfrac{SS_{model}/df_{model}}{SS_{error}/df_{error}}$

- and $SS_{total} = SS_{model} + SS_{error}$

- how do we obtain SS_{total}, SS_{error}, and SS_{model}?

F-test for two groups

- SS_{total} represents score deviations from grand mean (M_Y)

$$SS_{total} = \sum (Y - M_Y)^2$$

- SS_{error} represents the deviations of each score from its group mean

$$SS_{error} = \sum (Y - \hat{Y})^2 = \sum (Y - M_{group})^2$$

- SS_{model} represents the **gains** we get if we substitute each score with the group mean instead of the grand mean

$$SS_{model} = \sum \sum n_i (M_{group} - M_Y)^2 = SS_{total} - SS_{error}$$

NHST for two independent groups (F-test)

step 1: state the hypotheses	step 2: set criteria for decision	step 3: collect data	step 4: make a decision!

$H_0: \mu_2 - \mu_1 = 0$
$H_1: \mu_2 - \mu_1 \neq 0$

$\alpha = .05$
find $F_{critical}$ based on **<u>right</u>** tailed test and degrees of freedom
$df_1 = k - 1$
$df_2 = n - k$

(1) compute SS_{model} and SS_{error}

(2) compute $F_{observed} = \frac{MS_{model}}{MS_{error}}$

(3) find p-value for F-score

check whether F is beyond $F_{critical}$ and p-value < .05. if so, reject null hypothesis!

activity: F-test for iris dataset

- conduct the F test for the iris dataset

F-test for iris dataset

- **step 1: state the hypotheses**

  - H$_0$: $\textcolor{red}{\mu_{virginica} - \mu_{setosa} = 0}$: petal lengths for both species are equal

  - H$_1$: $\textcolor{green}{\mu_{virginica} - \mu_{setosa} \neq 0}$: petal lengths for species are different

- **step 2: set criteria for decision**

  $k = 2$: number of levels of independent variable OR estimated parameters

  $$df_1 = k - 1 = 2 - 1 = 1$$

  $$df_2 = n - k = 20 - 2 = 18$$

  $$F(df_1, df_2) = F(1,18) = F_{critical} = 4.414$$
step 3a: obtaining SS_{total}

- what is SS_{total}? SS_{total} is the error left over after the grand mean has been fit to the data

$$SS_{total} = \sum (Y - M_Y)^2$$

- for iris, SS_{total} = 76.218

step 3b: obtaining SS_{error}

- SS_{error} is the error that is left over after our species model has been fit

- our species model substitutes each raw score with the mean of the specific species

- $SS_{error} = \sum(Y - \hat{Y})^2 = \sum(Y - M_{group})^2$
- for iris, SS_{error} = .946

Species	Petal.Length(Y)	Yhat
setosa	1.4	1.45
setosa	1.4	1.45
setosa	1.3	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.7	1.45
setosa	1.4	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.5	1.45
virginica	5.6	5.33
virginica	5.1	5.33
virginica	5.1	5.33
virginica	5.9	5.33
virginica	5.7	5.33
virginica	5.2	5.33
virginica	5	5.33
virginica	5.2	5.33
virginica	5.4	5.33
virginica	5.1	5.33

step 3c: obtaining SS_{model}

- how can we obtain SS_{model}?

$$SS_{total} = SS_{model} + SS_{error}$$

thus, $SS_{model} = SS_{total} - SS_{error}$

- for iris, SS_{total} = 76.218 and SS_{error} = .946

- SS_{model} = 75.272

Species	Petal.Length(Y)	Yhat
setosa	1.4	1.45
setosa	1.4	1.45
setosa	1.3	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.7	1.45
setosa	1.4	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.5	1.45
virginica	5.6	5.33
virginica	5.1	5.33
virginica	5.1	5.33
virginica	5.9	5.33
virginica	5.7	5.33
virginica	5.2	5.33
virginica	5	5.33
virginica	5.2	5.33
virginica	5.4	5.33
virginica	5.1	5.33

step 3d: obtaining $F_{observed}$

- $F_{observed} = \frac{MS_{model}}{MS_{error}} = \frac{SS_{model}/df_{model}}{SS_{error}/df_{error}} = 1432.24$

- p-value = <.0001

- $F_{critical} = 4.414$

- thus, $F(1,18) = 1432.24$, p < .0001

  - we can reject the null hypothesis

  - petal lengths of setosa and virginica are significantly different

  - also, $t^2 = F$!!

Species	Petal.Length(Y)	Yhat
setosa	1.4	1.45
setosa	1.4	1.45
setosa	1.3	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.7	1.45
setosa	1.4	1.45
setosa	1.5	1.45
setosa	1.4	1.45
setosa	1.5	1.45
virginica	5.6	5.33
virginica	5.1	5.33
virginica	5.1	5.33
virginica	5.9	5.33
virginica	5.7	5.33
virginica	5.2	5.33
virginica	5	5.33
virginica	5.2	5.33
virginica	5.4	5.33
virginica	5.1	5.33

F-table

	SS	df	MS	F	p-value

testing more than two groups

- an independent groups t-test is a special case of linear models (Y = a + bX) when X is nominal

- it is *also* a special case of only comparing two groups

- example of comparing more than two groups?

revisiting iris

Iris setosa *Iris versicolor* *Iris virginica*
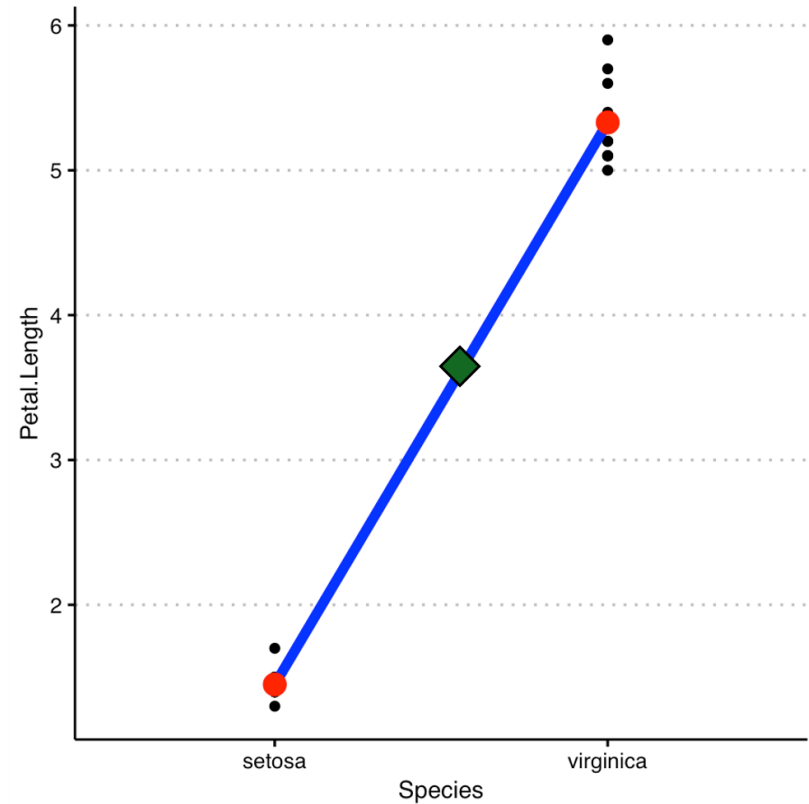

- recall that the iris dataset actually contains information about three species (setosa, virginica, and versicolor)

Iris setosa *Iris versicolor* *Iris virginica*
revisiting iris
- what if we wanted to look at all three species?

- how many possible comparisons are involved?

  - $M_{virginica} - M_{setosa}$

  - $M_{versicolor} - M_{setosa}$

  - $M_{virginica} - M_{versicolor}$

- we could fit individual linear models for each comparison and conduct the t-test/F-test for each comparison
multiple tests and type I errors
- each time a hypothesis test is conducted with some α-level, there is α % probability of making a type I error

- as more tests are conducted, this probability increases
  - P(type I error in one test) = α
  - P (no type I error in one test) = $1 - \alpha$
  - P (no type I error in m tests) = $(1 - \alpha)^m$
  - P (at least one type I error in m tests) = $1 - (1 - \alpha)^m$
- two solutions
  - correct for multiple comparisons
 - do an "overall" test before jumping in
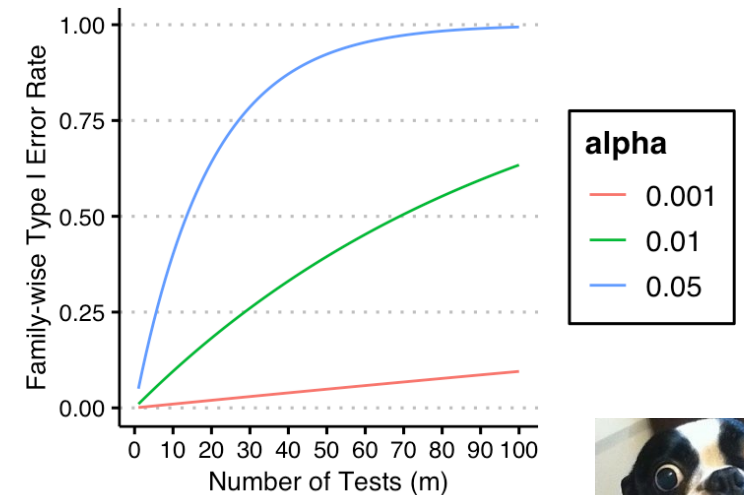

F test aka ANOVA!

- we already saw how an analysis of variance / F-test can help us assess "overall" fit of the model

- formally, ANOVA is a *generalized* t-test for more than two means/groups!

- we first evaluate whether the overall model explains variance over and above random chance

  - $F = \dfrac{MS_{model}}{MS_{error}} = \dfrac{SS_{model}/df_{model}}{SS_{error}/df_{error}}$

  - If F > 1, the group differences are greater than what would be expected as random variation within groups

- if this test is significant, we then go in to look for pairwise differences between groups

Between-group variation
(i.e. Differences among group means)

Within-group variation
(i.e. Variability within each group)

types of ANOVAs = complex linear models

- n (independent variables)
  - one-way: one independent variable
  - two-way / three-way
  - (n>3)-way: crazy land
- within or between subjects
  - between subjects: regular ANOVA
    - independent observations: each raw score comes from *different* individuals!
  - within-subjects: repeated measures ANOVA
    - non-independent observations: multiple raw scores from from the same individuals

Between-group variation
(i.e. Differences among group means)

Value

Within-group variation
(i.e. Variability within each group)

Value

revisiting iris

- when more than two groups are involved, we need to expand our model to include multiple groups

- petal length = a + b (virginica) + c (versicolor)
  - a = M_{setosa}
  - b = $M_{virginica} - M_{setosa}$
  - c = $M_{versicolor} - M_{setosa}$
NHST for one-way ANOVA

- **step 1: state the hypotheses**

  - H_0: no change in mean petal lengths due to species, i.e., $\mu_{setosa} = \mu_{virginica} = \mu_{versicolor}$
  - H_1: there is at least one mean difference (no claims about where!)

- **step 2: set criteria for decision**

$$F(df_1, df_2) = F_{critical}$$

- **step 3: collect data**

- **step 4: make a decision!**

NHST for one-way ANOVA

step 1:
state the
hypotheses

step 2:
set criteria
for decision

step 3:
collect
data

step 4:
make a
decision!

$H_0: \mu_1 = \mu_2 = \cdots = \mu_n$
$H_1: at\ least\ one\ mean\ difference$

$\alpha = .05$
find $F_{critical}$ based
on **right** tailed test
and degrees of
freedom
$df_1 = k - 1$
$df_2 = n - k$

(1) compute SS_{model} and SS_{error}

(2) compute $F_{observed} = \frac{MS_{model}}{MS_{error}}$

(3) find p-value for F-score

check whether F is
beyond $F_{critical}$ and
p-value < .05. if so, reject
null hypothesis!

step 2: set criteria for decision

- we need to find the values of df_1 and df_2 and the corresponding critical F value

$$F(df_1, df_2) = F_{critical}$$

- k denotes the number of levels of the independent variable OR estimated parameters

    - $df_{model} = k - 1 = 3 - 1 = 2$

    - $df_{error} = n - k = 30 - 3 = 27$

- $F_{critical} = F(df_1, df_2)$ at α = 0.05

- $F(2,27)$ at α = 0.05 = 3.59

step 3: obtaining $F_{observed}$

- we need to obtain estimates of

$$F_{observed} = \frac{MS_{model}}{MS_{error}} = \frac{SS_{model}/df_{model}}{SS_{error}/df_{error}}$$

- $SS_{total} = SS_{model} + SS_{error}$

  - SS_{total} represents error left over after grand mean

  - SS_{error} represents error left over after species mean model

  - $SS_{model} = SS_{total} - SS_{error}$

step 3: obtaining $F_{observed}$

- SS_{total} represents deviations from grand mean (M_Y)

$$SS_{total} = \sum (Y - M_Y)^2$$

- SS_{error} represents the deviations of each score from its group mean

$$SS_{error} = \sum (Y - \hat{Y})^2 = \sum (Y - M_{group})^2$$

- SS_{model} represents the **gains** we get if we substitute each score with the group mean instead of the grand mean

$$SS_{model} = \sum \sum n_i (M_{group} - M_Y)^2 = SS_{total} - SS_{error}$$

step 3 and 4: obtaining F & decisions

- calculate each of these for iris

  - SS_{total}= 84.76

  - SS_{error} = 3.087

  - SS_{model}= 81.67

- calculate $F_{observed} = \dfrac{MS_{model}}{MS_{error}} = \dfrac{SS_{model}/df_{model}}{SS_{error}/df_{error}} = 357.1778$, $p < .0001$

- $F_{critical}$ = 3.59 at α = 0.05

- therefore, the null hypothesis can be rejected! i.e., species differ in their petal lengths

- $F(2,27) = 357.18, p < .0001$

F-table

	SS	df	MS	F	p-value
SS_{model} species	81.67	2	75.272	357.1778	<.0001
SS_{error} residual	3.087	27	0.0526		

```
Response: Petal.Length
           Sum Sq Df F value    Pr(>F)
Species    81.675  2  357.18 < 2.2e-16 ***
Residuals  3.087 27
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

what now?

- once we know that the "overall" test has detected something meaningful, we can look for specific differences by conducting pairwise t-tests

  - $M_{virginica} - M_{setosa}$

  - $M_{versicolor} - M_{setosa}$

  - $M_{virginica} - M_{versicolor}$

- BUT...what about the type I error??

- we correct for multiple comparisons
post-hoc tests

- when pairwise t-tests are conducted after an "overall" / omnibus test (ANOVA), they are called post-hoc tests

- several corrections exist in the literature

  - Tukey's Honest Significant Difference Test: moderately conservative

  - Scheffe's test: very conservative

  - Fisher LSD: very liberal

- most statistical software will allow you to apply a correction, so we will not cover the specifics

- visual inspection is useful in these situations
one-way ANOVA assumptions

- independent observations within each sample

- normality

- homogeneity of variances
next time

- **before** class
  - *watch:* Hypothesis Testing (two-groups: F-test) [12 min]
  - *watch:* Hypothesis Testing (one-way ANOVA: F-test) [18 min]
  - *read*: [optional] Read Chapter 14 from the Gravetter & Wallnau (2017) textbook.
  - *start*: Problem Set #6 (Chapter 10 and Chapter 12 problems)
- **during** class
  - two independent variables / two-way ANOVA
