

# DATA ANALYSIS

Week 11: Special cases (one sample z and t-test)

# today's agenda

hypothesis testing with a  
single mean

# general hypothesis testing approach

- we want to explain some variation in the world/population
- we take a sample and obtain a sample statistic based on an underlying model
- we then assume that our model is wrong / unnecessary
- we create a (hypothetical) sampling distribution of the sample statistic
- we ask what are likely and unlikely values of the sample statistic under this assumption
- we assess the likelihood of the observed sample statistic under this sampling distribution
- we make the decision to reject or fail to reject the “null” assumption

# our progress so far

$\text{data} = \text{model} + \text{error}$

thus far

- $\text{data} = \text{mean} + \text{error}$
- $\text{data} = X \text{ (interval/ratio)} + \text{error}$
- $\text{data} = X \text{ (nominal)} + \text{error}$

after midterm 2

- $\text{data} = X + Y + \text{error}$
- $\text{data (NOIR)} = \text{model (NOIR)} + \text{error}$

# our progress so far

data = model + error

correlation t-test  
or  
regression F-test

thus far

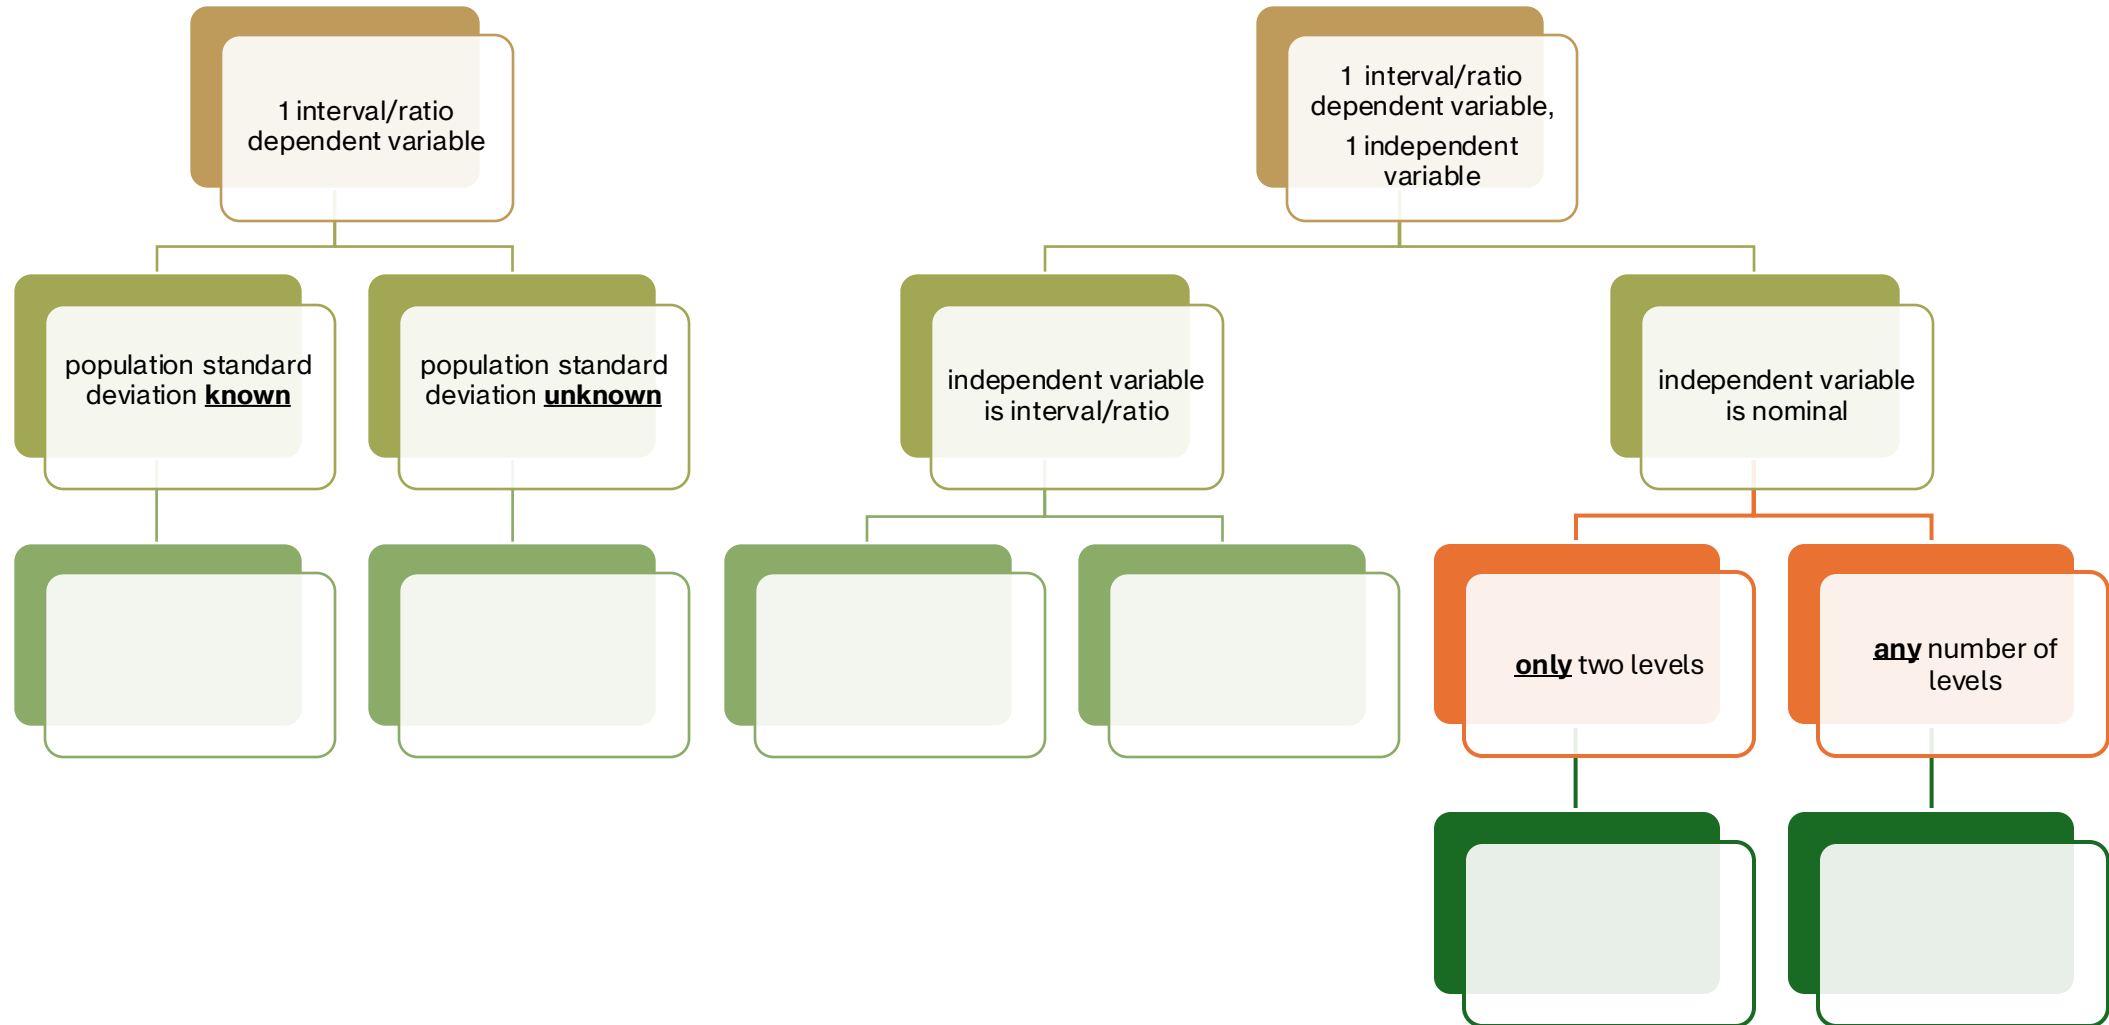

- data = mean + error
- data = X (interval/ratio) + error
- data = X (nominal) + error

ANOVA F-test

after midterm 2

- data = X + Y + error
- data (NOIR) = model (NOIR) + error

# hypothesis testing flowchart

# sampling with means

- the average mother sea turtle lays  $\mu = 80$ ,  $\sigma = 6$  eggs per mating season. We work for an endangered species foundation, and are testing the effectiveness of a new hormone (X15) on turtle fertility. We predict that turtles treated with the hormone will produce *different* nest sizes from the average turtle (no direction). We collect a sample of  $n=30$  turtles from the above population and treat them with the hormone. We then count the number of eggs in their nest and get a mean of 84.
- is the fertility hormone effective?

# framing the problem

- population characteristics (usual turtles):  $\mu = 80, \sigma = 6$
- sample characteristics (our 30 turtles):  $M = 84$
- two possible explanations for the difference in sample mean ( $M$ ) and population mean ( $\mu$ )
  - sampling error ( $H_0$ : null hypothesis)
  - true effect of hormone ( $H_1$ : alternative hypothesis)
- we assume the null hypothesis is true and set out to reject this assumption with our evidence

# sampling with means

- we know some things about the population
- $\mu = 80, \sigma = 6$
- we could take random samples from this original population and examine the distribution of means
- sampling distribution of means

# sampling with means

- we know some things about the population
- $\mu = 80, \sigma = 6$
- we could take random samples from this original population and examine the distribution of means
- sampling distribution of means
- once we know the **form of this sampling distribution (t / F / normal)**, we can assess the probability of obtaining a sample as or more extreme as ours

# central limit theorem (CLT)

- the **central limit theorem** states that for **any** population with mean  $\mu$  and standard deviation  $\sigma$ , the **distribution of sample means** for sample size  $n$  will have:
  - a mean of  $\mu_M = \mu$  = expected value of M
  - a standard deviation of  $\sigma_M = \frac{\sigma}{\sqrt{n}}$  = standard error of the mean or M
  - will approach a normal distribution as  $n$  approaches infinity
  - distribution of sample means will be normally distributed **even if the population was not normally distributed (if  $n$  is large enough!)**
  - typically  $n$  (number of scores in a sample) around 30 yields a reasonably normal distribution
- CLT only applies to the **distribution of sample means**, i.e., if our sample statistic is NOT a mean, and our hypotheses are NOT about means, then we must use a different sampling distribution for the null hypothesis

# typical sampling distributions

sample statistic	sampling distribution	standard error
means	normal (central limit theorem)	$\sigma_M = \frac{\sigma}{\sqrt{n}}$
slopes / correlation	Student's $t$ distribution	$SE_r = s_r = \sqrt{\frac{1 - r^2}{n - 2}}$ $SE_{model} = \sqrt{\frac{SS_{error}}{n - 2}}$
ratio of squared errors	F-distribution	$F_{observed} = \frac{MS_{model}}{MS_{error}}$

# step 1: stating the hypotheses

- **null hypothesis:** X15 does not have an effect on nest size, i.e., it stays the same and any variation observed in samples is simply due to sampling error

$$H_0: \mu = 80$$

- **alternative hypothesis:** X15 has an effect on nest size

$$H_1: \mu \neq 80$$

# step 2: set criteria for decisio

- examine the distribution of sample means
- the **central limit theorem** states that for **any** population with mean  $\mu$  and standard deviation  $\sigma$ , the **distribution of sample means** for sample size  $n$  will have:
  - a mean of  $\mu_M = \mu$  = expected value of  $M = 80$
  - a standard deviation of  $\sigma_M = \frac{\sigma}{\sqrt{n}} = \frac{6}{\sqrt{30}} = 1.095$
- represent the problem graphically
- criteria:  $\alpha$ -level = .05 (extreme 5%)
- find  $z_{\text{critical}} = \pm 1.96$ ,  $p_{\text{critical}} = .05$  ([calculator](#))
- for a **p-value** smaller than .05, the obtained sample mean is unlikely to have come from this expected sampling distribution for the null hypothesis

t value   **z value**   chi-square value   f value

-1.6448536

z value for Two Tailed Probability:  
-1.959964 & 1.959964

# step 3 and 4: collect data and decide!

- we collect the data and evaluate the probability of obtaining the data as extreme as this, under the null hypothesis
  - $P(\text{data} \mid \text{null})$
  - **compute z-score** of sample mean under the sampling distribution
  - $$Z_{\text{observed}} = \frac{M - \mu}{\sigma_M} = \frac{84 - 80}{1.095} = 3.65$$
  - remember that  $z_{\text{critical}} = \pm 1.96$
  - look up the probability,  $p_{\text{observed}} < .001$
  - this sample is very rare if the null hypothesis was true
- conclusion: we reject the null hypothesis that the hormone does not produce a difference
- reporting: X15 has a **significant effect** on sea turtle fertility ( $M = 84$ ,  $z = 3.65$ ,  $p < .001$ )

# W11 Activity 1

- [complete on Canvas](#)

# W11 Activity 1a

- If the final exam scores for the population have a standard deviation of  $\sigma = 12$ , does the sample provide enough evidence to conclude that the new online course is significantly different from the traditional class? Use a two-tailed test with  $\alpha = .05$ .

# step 1: stating the hypotheses

- **null hypothesis**: the new online course does not produce any change in scores compared to the traditional class and any variation observed in samples is simply due to sampling error

$$H_0: \mu = 71$$

- **alternative hypothesis**: the new online course is significantly different from the traditional class

$$H_1: \mu \neq 71$$

## step 2: set criteria for decision

- examine the distribution of sample means
- $n = 36$
- $\mu_M = \mu = \text{expected value of } M = 71$
- $\sigma_M = \frac{\sigma}{\sqrt{n}} = \frac{12}{\sqrt{36}} = 2$
- criteria:
  - $\alpha\text{-level} = .05$
  - $z_{\text{critical}} = \pm 1.96$  (extreme 5%)

# step 3 and 4: collect data and decide!

- compute z-score of this mean under the sampling distribution

- $z_{observed} = \frac{M - \mu}{\sigma_M} = \frac{76 - 71}{2} = 2.5$

- $p_{observed} = .012$

- remember that  $z_{critical} = \pm 1.96$  and  $\alpha = .05$

- this sample is very rare if the null hypothesis was true
- conclusion: we reject the null hypothesis
- reporting: online course has a significant effect on scores ( $z = 2.5, p = .012$ )

Z=2.5

The two-tailed P value equals 0.0124

By conventional criteria, this difference is considered to be statistically significant.

# W11 Activity 1b

- If the final exam scores for the population have a standard deviation of  $\sigma = 12$ , does the sample provide enough evidence to conclude that the new online course is significantly different from the traditional class? Use a two-tailed test with  $\alpha = .01$ .

# what changes?

- step 1: stating the hypotheses (same!)
- step 2: set criteria for decision
  - $n = 36$
  - $\mu_M = \mu = \text{expected value of } M = 71$
  - $\sigma_M = \frac{\sigma}{\sqrt{n}} = \frac{12}{\sqrt{36}} = 2$
  - $z_{\text{critical}}$  based on  $\alpha = .01 = \pm 2.58$
  - $p_{\text{critical}} = .01$
- step 3: collect data (same!)
  - $z_{\text{observed}} = \frac{M - \mu}{\sigma_M} = \frac{76 - 71}{2} = 2.5$
  - $p_{\text{observed}} = .012$
- step 4: decide
  - $z_{\text{observed}} < z_{\text{critical}}$  and  $p_{\text{observed}} > p_{\text{critical}}$
  - cannot reject the null hypothesis!

# W11 Activity 1c

- If the population standard deviation is  $\sigma = 18$ , is the sample sufficient to demonstrate a significant difference? Again, use a two-tailed test with  $\alpha = .05$ .

# what changes?

- step 1: stating the hypotheses (same!)
- step 2: set criteria for decision
  - $n = 36$
  - $\mu_M = \mu = \text{expected value of } M = 71$
  - $\sigma_M = \frac{\sigma}{\sqrt{n}} = \frac{18}{\sqrt{36}} = 3$
  - $z_{\text{critical}} = \pm 1.96$
- step 3: collect data
  - $z_{\text{observed}} = \frac{M - \mu}{\sigma_M} = \frac{76 - 71}{3} = 1.67$
  - $p_{\text{observed}} = .0475 + .0475 = .095$
- step 4: decide
  - $z_{\text{observed}} < z_{\text{critical}}$
  - cannot reject the null hypothesis!

$$Z=1.67$$

The two-tailed P value equals 0.0949

# W11 Activity 1d

- If the population standard deviation is  $\sigma = 18$ , is the sample sufficient to demonstrate that online courses **increases** the score compared to traditional class? Use a one-tailed test with  $\alpha = .05$ .

# what changes?

- **step 1: stating the hypotheses**
  - $H_1: \mu > 71$  and  $H_0: \mu \leq 71$
- **step 2: set criteria for decision**
  - $n = 36, \mu_M = \mu = \text{expected value of } M = 71$
  - $\sigma_M = \frac{\sigma}{\sqrt{n}} = \frac{18}{\sqrt{36}} = 3$
  - $z_{\text{critical}} = +1.65$  (only one side)
- **step 3: collect data**
  - $z_{\text{observed}} = \frac{M - \mu}{\sigma_M} = \frac{76 - 71}{3} = 1.67$
  - $p_{\text{observed}} = \frac{.0949}{2} = .0475$
- **step 4: decide**
  - $z_{\text{observed}} > z_{\text{critical}}$
  - we can reject the null hypothesis if we use a one-tailed test!

## Results

z value:

1.6449

z value for Right Tailed Probability:

1.6448536

z value for Left Tailed Probability:

-1.6448536

z value for Two Tailed Probability:

-1.959964 & 1.959964

Z=1.67

The two-tailed P value equals 0.0949

# summary

- making the critical region region smaller (by decreasing the  $\alpha$ -level) makes the z-test more conservative, i.e.,  $z_{\text{critical}}$  will be higher, making it harder to reject the null hypothesis
- higher standard errors (due to high population variance  $\sigma$  or low sample size  $n$ ) will impact the sample z-score ( $z_{\text{observed}}$ ), i.e., where the sample statistic lies relative to the distribution

$$z = \frac{M - \mu}{\sigma_M} \text{ and } \sigma_M = \frac{\sigma}{\sqrt{n}}$$

# Cohen's d: effect size for means

- hypothesis testing depends on sample sizes - higher sample sizes typically lead to statistically significant effects, even if those effects may be small
- effect sizes are a way to quantify the magnitude of the effect independent of sample size

- Cohen's d: effect size for means

- Cohen's  $d = \frac{\text{mean difference}}{\text{standard deviation}} = \frac{M - \mu}{\sigma}$

Magnitude of $d$	Evaluation of Effect Size
$d = 0.2$	Small effect (mean difference around 0.2 standard deviation)
$d = 0.5$	Medium effect (mean difference around 0.5 standard deviation)
$d = 0.8$	Large effect (mean difference around 0.8 standard deviation)

# one sample: z to t-distribution

- inferential statistics = from samples to populations
- but...for a one-sample z-test, we need to know the mean ( $\mu$ ) and standard deviation ( $\sigma$ ) of the population! this information is usually not known!
- when  $\sigma$  is unknown and we have to rely on sample standard deviation ( $s$ ) as an estimator, we cannot use the normal distribution as our sampling distribution

$$\sigma_M = \frac{\sigma}{\sqrt{n}} \text{ vs. } s_M = \frac{s}{\sqrt{n}}$$

- we instead use the student's  $t$  distribution
- estimated Cohen's  $d = \frac{M - \mu}{s}$

# z-test vs. one-sample t-test

## z-tests

- **when:** population mean and standard deviation are known
- **want to compare:** sample mean to population mean

## one sample t-test

- **when:** population standard deviation is unknown
- **want to compare:** sample mean to population mean

# W11 Activity 2

- [complete on Canvas](#)

# W11 Activity 2a

- research examining the effects of preschool childcare has found that children who spent time in day care, especially high-quality day care, perform better on math and language tests than children who stay home with their mothers (Broberg, Wessels, Lamb, & Hwang, 1997). In a typical study, a researcher obtains a sample of  $n = 10$  children who attended day care before starting school. The children are given a standardized math test for which the population mean is  $\mu = 50$ . The scores for the sample are as follows: 53, 57, 61, 49, 52, 56, 58, 62, 51, 56.
- Is this sample sufficient to conclude that the children with a history of preschool day care are significantly different from the general population? Use a two-tailed test with  $\alpha = .01$ .

# framing the problem

- population
  - mean  $\mu = 50$
  - **standard deviation ( $\sigma$ ) unknown, we cannot use a z-test**
- sample
  - $n = 10$ , sample scores:  $X = 53, 57, 61, 49, 52, 56, 58, 62, 51, 56$
  - sample mean:  $M = \frac{\sum X}{n} = 55.5$
  - sample standard deviation:  $s = \sqrt{\frac{(X-M)^2}{n-1}} = 4.249183$
- we need to use a t-test!
  - degrees of freedom:  $df = n - 1 = 9$
  - $s_M = \sqrt{\frac{s^2}{n}} = \sqrt{\frac{(4.249183)^2}{10}} = 1.34371$

# hypothesis testing

- step 1: stating the hypotheses
  - $H_0: \mu = 50; H_1: \mu \neq 50$
- step 2: setting decision criteria
  - [two-tailed test \(t-value calculator\)](#)
  - $t_{critical}(9) = \pm 3.2498$  for  $\alpha = .01$
- step 3: collect data
  - $t_{observed} = \frac{M - \mu}{s_M} = \frac{55.5 - 50}{1.34371} = 4.09$
  - $p_{observed} = 0.0027$  ([obtained from p-value calculator for t-score](#))
- step 4: decide!
  - $p_{observed} < .05$  and  $t_{observed} > t_{critical}(9)$
  - reject  $H_0$  and conclude that children with a history of preschool day care are significantly different from the general population,  $t(9) = 4.09, p = .003$ .

# W11 Activity 2b: Cohen's $d$

- *estimated*  $d = \frac{M - \mu}{s}$
- population mean  $\mu = 50$
- sample mean:  $M = \frac{\sum X}{n} = 55.5$
- sample standard deviation:  $s = \sqrt{\frac{(X - M)^2}{n - 1}} = 4.249183$
- $d = \frac{M - \mu}{s} = \frac{55.5 - 50}{4.249} = 1.29$
- Math achievement scores for children with a history of preschool day care are significantly different from the general population,  $t(9) = 4.09$ ,  $p = .003$ ,  $d = 1.29$ .

# W11 Activity 2c and 3d

3

Multiple Choice 1 point

Let's say I re-ran the study another 100 times. The distribution of sample means I will obtain from each of those studies will be:

- ☐ Normal
- ☐ t-distributed
- ☐ F-distributed
- ☐ Cannot be determined

4

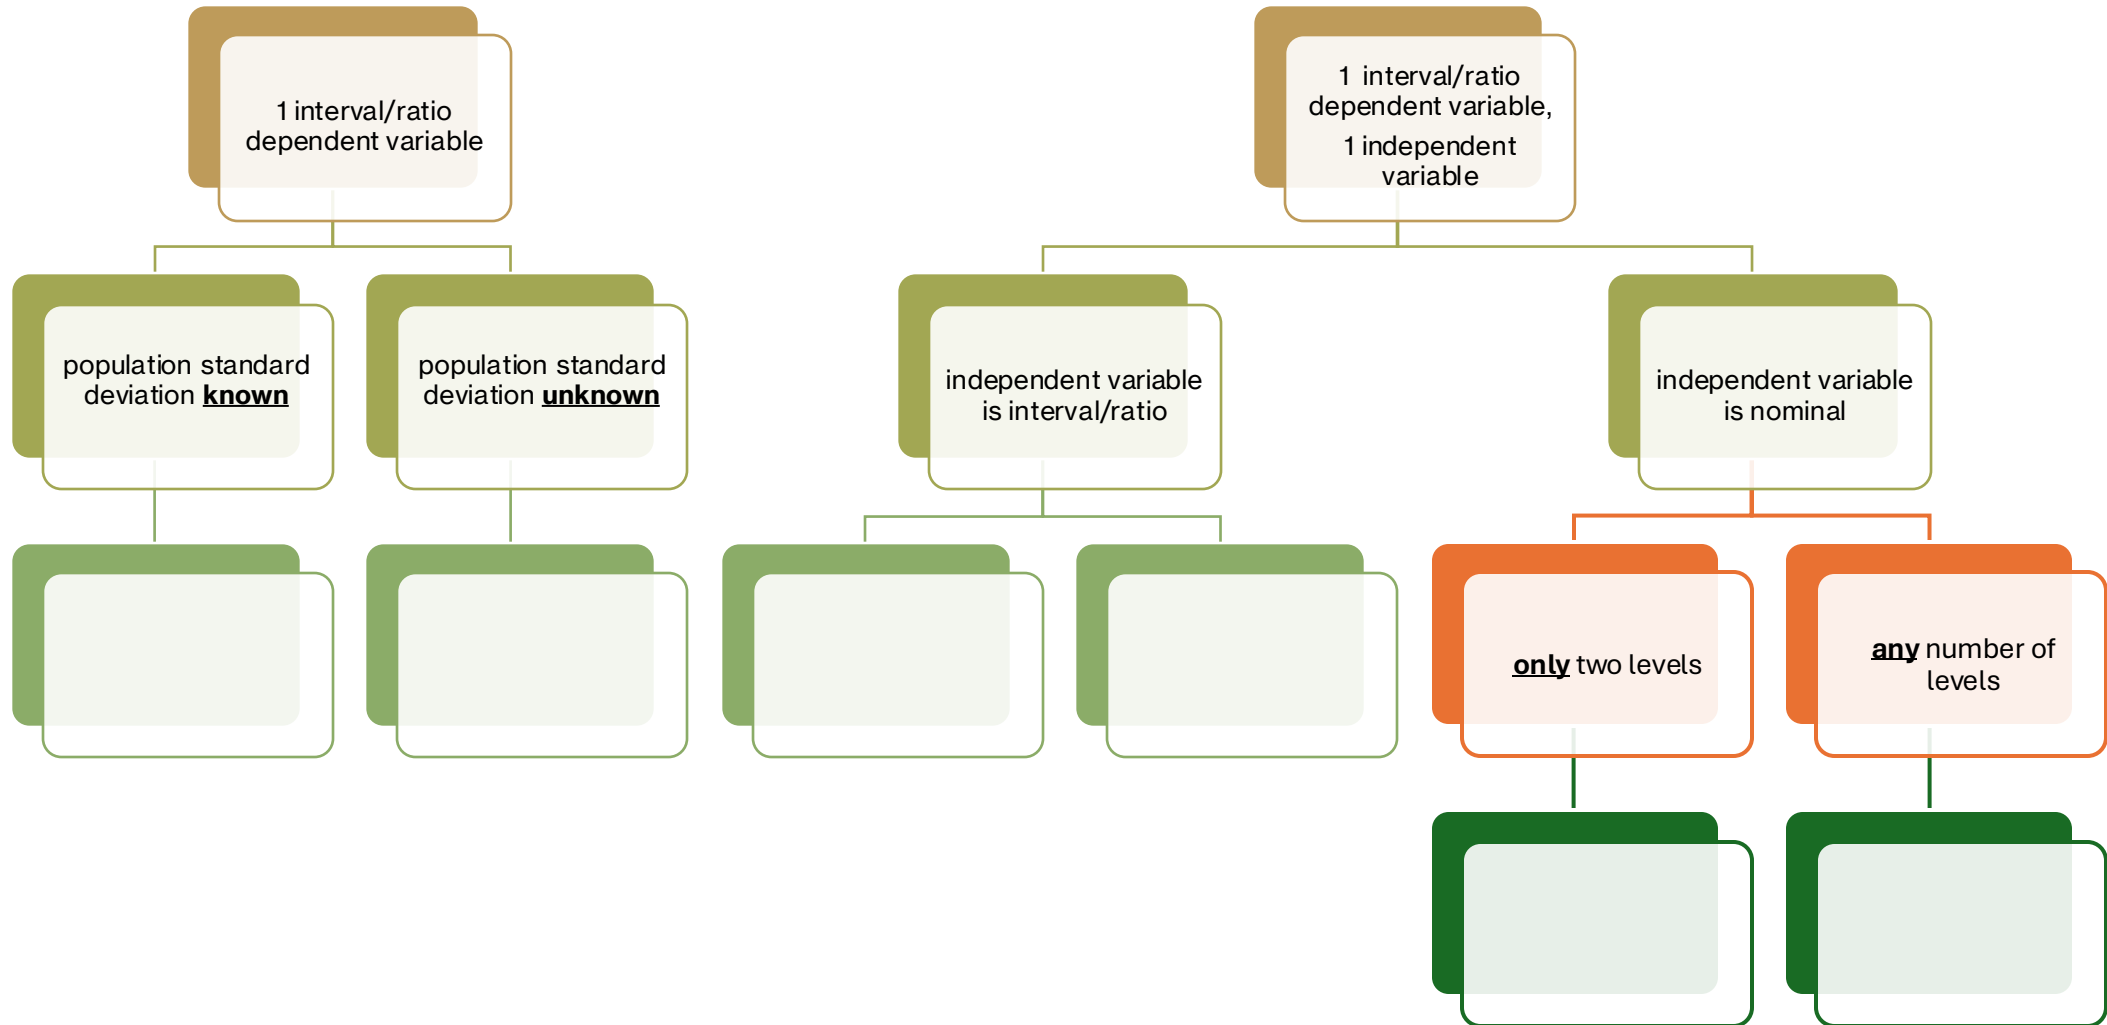

Multiple Choice 1 point

Let's say I re-ran the study another 100 times. If there was NO true effect of daycare in the population, the distribution of sample means I will obtain from each of those studies will have the mean:

- ☐ 50
- ☐ 55.5
- ☐ 10
- ☐ Impossible to know
